LEXINGTON

MASSACHUSETTS

The work reported in this document was performed at Lincoln Laboratory, a center for research operated by Massachusetts Institute of Technology. This research is a part of Project Vela Uniform, which is sponsored by the Advanced Research Projects Agency of the Department of Defense under Air Force Contract F19628-73-C-0002 (ARPA Order 512).

This report may be reproduced to satisfy needs of U.S. Government agencies.

ABSTRACT

A list of seismic events for the period 20 February to 19 March 1972 (The International Seismic Month - ISM) has been compiled using short-period data from a large number of seismic stations and arrays. Hypocenters and other parameters have been obtained for every event and are presented along with comparisons with other event lists for the same time period. Also included are the results of experiments designed to calibrate certain parameters which have been selected to indicate the accuracy of estimated depths and epicenters. The ISM list contains 996 verified events.

Accepted for the Air Force Eugene C. Raabe, Lt. Col., USAF Chief, ESD Lincoln Laboratory Project Office

INTERNATIONAL SEISMIC MONTH EVENT LIST

by R. T. Lacoss, R. E. Needham and B. R. Julian

Introduction

In January 1972 a group of seismologists from several countries met in Cambridge, Massachusetts, to discuss problems related to the seismic detection and identification of underground nuclear tests. Considerable interest was expressed at that time in a proposal that a cooperative attempt be made to better assess the capabilities of deployed seismic instrumentation for monitoring worldwide seismic activity. Shortly thereafter several groups of seismologists agreed to informally collaborate in such an undertaking. The period from 20 February to 19 March 1972 (The International Seismic Month - ISM) was selected for the experiment and the Lincoln Laboratory agreed to act as a data center.

The cooperating groups, more background, and some of the details of the Lincoln role can be found in an earlier report⁽¹⁾. Other reports of Lincoln activity and progress can be found in three Semiannual Technical Summaries ⁽²⁾, ⁽³⁾, ⁽⁴⁾. In the present report we give the complete and final list of events which occurred during the ISM and which we have been able to detect and locate using available seismic data. Also included for each event are the parameters assigned to the same events by the USGS PDE (U. S. Geologic Survey Preliminary Determination of Epicenters), the LASA (Large Aperture Seismic Array in Montana) bulletin, the NORSAR (Norwegian Seismic Array) bulletin, and an bulletin generated by a selected set of only 32 stations. Comparison between the ISM list and these others are given. No long-period data is presented or analyzed in this report.

The Data

Appendix I contains the list of 996 ISM events. The data for each event are listed in columns. For each event there are 60 parameters given. These parameters include the actual ISM parameters, USGS PDE parameters, LASA and NORSAR bulletin parameters, and parameters obtained using a selected set of 32 stations. Parameter names are listed in the leftmost column of each page and the definition of each of the parameters is presented at the start of the Appendix. Figure 1 is a map of the 996 epicenters in the ISM event list.

Appendix II is a chronological listing of all LASA and NORSAR bulletin entries which could not be verified or associated with any of the 996 ISM events. These events may be real but we have not been able to verify them with data from other stations. Table I shows in summary form the number of events from various event lists which correspond to ISM events and which are unverified by the ISM list.

TABLE 1

SOURCE	ENTRIES IDENTIFIED WITH ISM EVENTS	UNVERIFIED ENTRIES
USGS PDE	353	2*
LASA BULLETIN	559	96
NORSAR BULLETIN	361	35
32 STATION ISM	818	0
ISM LIST	996	0

^{*} One event located by USGS using no station more than 3° from epicenter was excluded from the ISM as purely local. The other, in South Africa, required use of P_g for location and our program did not have this option.

Fig. 1. Map of ISM epicenters.

Almost 200 stations were used in generating the ISM event list. When the list was completed the contributions of all stations were reviewed and a set of only 32 was selected to determine the utility of such a smaller network. Station selection was ad hoc to give good global coverage while using stations which contributed data to large numbers of ISM events. The list of 32 stations and some indication of their contribution to the full ISM are given in Table II. The rightmost column lists the number of ISM events with which the arrivals from that station could be associated. The next column tells how many arrivals were associated with the ISM events. The first numerical column gives the number of arrivals reported by the station. In the case of NORSAR and LASA this last is very large because reports of signal arrivals were obtained from internal array detection logs as well as from the array bulletins. In this report any reference to a 32 station list is to the list of events which could be generated using only data available from these 32 stations.

Of all of the short-period stations used in the ISM only LAO, NAO, HFS, KBL, and CHG and all Canadian stations were specifically read by an analyst or in some other way treated especially for the ISM. For all other stations only picks routinely submitted by the station to USGS for PDE were used. In general, as can be seen to some extent in Table II, the stations given special treatment tended to contribute to more events and to contribute more arrivals to the data base. We would have wished that all stations could be carefully picked for small events and that recording quality could be improved and filtering could be done. Unfortunately this was not possible and our list represents only the best we could do with available data and resources.

Event Grades

The origin times, hypocenters, and m_b values for events in the ISM are not all equally reliable estimates of those parameters for different events. An attempt has been made to assign grades to events according to the probable reliability of the listed ISM event parameters. Eight grades have been defined and are included in the data of Appendix I. Grades A, B, C, D are for events which could be located without arbitrarily restraining depth. Whenever possible each ISM event has been located by an unrestrained nonlinear weighted least squares fit of reported arrival times and horizontal phase velocities at arrays. All major phases, including depth phases such as pP and pPKP, were treated in the same way by the programs. Any event for which convergence could be obtained with depth greater than zero and less than seven hundred kilometers was assigned a grade of A, B, C, or D. Events which could be located only by arbitrarily restraining depth to zero, seven hundred, or some value in between was assigned a grade of AI, BI, CI, or DI. The I indicates that the depth is indeterminate in the sense just described.

The event grades are based upon six different parameters. These are:

NAVEMB: The number of individual station $\mathbf{m}_{\mathbf{b}}$ values averaged to obtain the ISM $\mathbf{m}_{\mathbf{b}}$ value.

DEGF: Degrees of freedom in the location and origin time estimates. This is equal to the number of scalar observations used in the location minus the number of parameters estimated (three for AI, BI, CI, DI events and four for A, B, C, D events).

RATIO: A measure of the goodness of fit of the observations to

the estimated origin time and location parameters.

Residuals were weighted inversely by their assigned standard deviations, squared, summed, and divided by DEGF to obtain RATIO.

MAXAX2:

Largest principal semiaxis of our estimated epicenter error ellipse. This parameter has kilometers as units and can be calculated only for A, B, C, or D events. Results of some experiments designed to calibrate this parameter, and DEPTHQ which is discussed below, are presented in the final section of this report but more research is required to establish its true meaning and utility. Additional discussion of the error estimation problem will be found in Reference 3.

DEPTHQ:

Half length of our estimated depth error bar. It is calculated only for A, B, C, D events and has units of kilometers. It indicates the relative reliability of depths but like MAXAX2 requires further research for absolute calibration and verification of its ultimate utility.

DEPTH: Th

The ISM assigned depth for an event in kilometers.

The exact definition of grades in terms of the above parameters are given in Table III. For each grade all conditions must be met. The number of events in each grade is given in parenthesis in the table.

TABLE III

Grading Rules

Depth Free for Convergence

Depth Fixed for Convergence

Grade = A (306)

Grade = AI (71)

 $MAXAX2 \le 100$

 $RATIO \le 1$

 $RATIO \le 2$

DEGF ≥5

DEGF ≥4

NAVEMB ≥3

DEPTHQ/DEPTH≤0.5 or DEPTHQ≤25

NAVEMB ≥ 3

Grade = B(34)

Grade = BI (16)

 $MAXAX2 \le 100$

 $RATIO \leq 1$

 $RATIO \le 2$

DEGF ≥ 5

DEGF ≥ 4

NAVEMB = 1 or 2

DEPTHQ/DEPTH≤ 0.5 or DEPTHQ≤25

NAVEMB = 1 or 2

Grade = C (83)

Grade = CI (40)

 $MAXAX2 \le 100$

RATIO > 1

 $RATIO \le 2$

 $RATIO \le 2$

DEGF ≥ 4 DEPTHQ/DEPTH > 0.5 DEGF ≥ 5 $NAVEMB \ge 1$

DEPTHQ > 25

NAVEMB ≥ 1

Grade = D (197)

Grade = DI (249)

All run free which are

All fixed depth which are not AI, BI, or CI.

not A, B, or C.

The transition from Grade A to D is fairly clear. That is:

- A: Reliable hypocenter and mh
- B: Reliable hypocenter but perhaps less reliable m
- C: Reliable epicenter but perhaps less reliable depth as well as m
- D: All others.

The transition is more arbitrary and less clear for AI to DI. First note that DEGF ≥ 5 for AI, BI, CI, whereas it is DEGF ≥ 4 for A, B, C. In effect, this means we must have at least eight observations used for location in all cases. For AI, BI, we require RATIO ≤ 1 rather than RATIO ≤ 2 in the hope that tighter control on that parameter will compensate for not having DEPTHQ or MAXAX2. In case CI we include events with $1 < \text{RATIO} \leq 2$ in place of relaxing the depth control parameters which are not available. The transition in terms of NAVEMB is unchanged for I events. We should note that for many purposes events in grades AI, BI, and CI and even many in DI probably have good depths. That is, shallow depths are probably good within a few tens of kilometers and deep events do get listed as deep. Unfortunately this is a subjective and unsubstantiated assertion.

The definition of grades is somewhat arbitrary and the grades themselves are intended simply as aids to users of the event list. One can obtain some indication of the possible reliability of event parameters from the grades and for some research purposes one may wish to consider only events with high reliability to minimize the effects of errors in the event parameters. Unfortunately, for actual discrimination purposes, it would not be possible to consider only events with high reliability as defined by the grades. For example there are 30 D or DI events with listed m_b greater than 4.5, and 5 with m_b greater than 5.0. Even restricting interest to the Asian

geographic region outlined on Figure 2 we find that of 40 events listed with $m_b^{\,\,\geq\,} 4.5$ there are three with grades D or DI.

The 32 station list has also been graded to indicate the possible reliability of the 818 events which could be located with only that set of stations. Table IV summarizes the 32 station grades in comparison to the full ISM grades. In terms of numbers of events we see that the two lists are about the same in the low reliability categories D and DI and the 32 station list has fewer events in the higher reliability categories.

TABLE IV

Grade Distribution of ISM and 32 Station Lists

Grade	Number of ISM Events	Number of 32 Station Events
A	306	237
AI	71	77
В	34	12
BI	16	7
С	83	26
CI	40	24
D	197	195
DI	249	240

Fig. 2 Outline of geographic area defined by seismic regions 19, 26, 27, 28, 29, 30, 41, 42, 48, 49.

mb and Detection Statistics

Figure 3 shows a cumulative histogram of the $m_{\tilde{b}}$ values (AVEMB) for the 859 ISM events for which we were able to determine magnitudes. It also shows a histogram for events within the Asian region defined on Figure 2. In the selected Asian region there were 215 events with $m_{\tilde{b}}$ assigned and 33 with no $m_{\tilde{b}}$ value determined.

It is often assumed that the log of the number of events in any region and time interval will vary linearly with m_b . One can then fit straight lines to histograms such as those on Figure 3 and estimate at what magnitude level the detection system seems to start missing events. Basham and Anglin $^{(5)}$ used preliminary ISM data for a region similar to that of Figure 2 and concluded that the cumulative 90% detection threshold for that region was about 4.0. Since incremental thresholds are normally 0.2 to 0.3 units higher $^{(6)}$ they estimated the 90% incremental threshold to be 4.3 for that region. The data of Figure 3 do not contradict the conclusion although this fitting of straight lines must be accepted with some scepticism as a method of estimating detection thresholds since it does use a theoretically unsubstantiated assumption about the linear variation of seismic activity with m_b .

Fitting the complete ISM cumulative occurrence of events to obtain a detection and location threshold is doubly bothersome. Not only must the straight-line assumption be accepted but it is even more difficult to find a straight region to fit with a straight line. However, if such a method is used, it is our estimate that the 90% cumulative threshold obtained is between 4.5 and 4.6 with the corresponding incremental threshold 0.2 to 0.3 m_b units higher.

Detection and location thresholds are discussed further on but first the ISM $\rm m_b$ (AVEMB) must be related to the PDE, LASA, and NORSAR bulletin values. Figure 4

Fig. 3. Cumulative histogram of complete ISM m_b (AVEMB) and for events limited to Asian seismic regions 19, 26, 27, 28, 29, 30, 41, 42, 47, 48, 49.

Fig. 4. Histogram of ISM m_b minus (a) PDE m_b , (b) LASA m_b , (c) NORSAR m_b , for events with m_b assigned by both sources involved.

Fig. 4. Continued.

Fig. 4. Continued.

shows histograms of the difference between the ISM m_b and the m_b 's from these other sources. These data hold no special surprises. The scatter between PDE and ISM is less than in the other two cases since both PDE and ISM often average several station values to get their m_b . The average deviation between ISM and PDE, LASA, NORSAR are 0.04, -0.05, and 0.14 units, respectively. Only the last, indicating NORSAR m_b values are high by 0.1 to 0.2 units, might be considered significantly different from zero to be of any concern. In general there is scatter between these various m_b values but no large biases.

Now that the relationship between these $m_{\rm b}$ values has been statistically characterized we can consider more data related to detection thresholds. Figure 5 shows a histogram of ISM events which did not appear on the USGS PDE list. From this and Figure 3 we estimate that the PDE 90% cumulative threshold is about 5.0 with the incremental 0.2 to 0.3 units higher. This estimate assumes that the ISM missed no events above $m_{\rm b}$ = 5.0 and that the scatter of $m_{\rm b}$ values can be ignored. It is consistent with what one would get using the fitting of straight-lines approach to PDE data itself.

Figure 6 contains histograms of possible events which appeared in the LASA and NORSAR bulletins for the ISM time period but which could not be verified sufficiently by other station reports to be included in the actual ISM list. The counts for events placed in the region of Asia defined by Figure 2 are indicated by the horizontal lines. Of course these events are unverified, poorly located, and all m_b values are for a single station. Nevertheless if Figure 6 is accepted on face value it is in rough agreement with the detection thresholds discussed above for the ISM. First consider the Asia region only. A 90% incremental threshold of $m_b = 4.2$ or 4.3 is consistent with

Fig. 5. Histogram of $m_{\mbox{\scriptsize b}}$ (AVEMB) for ISM events not reported by USGS PDE.

Fig. 6. Histograms of unverified large-array bulletin events. (a) LASA m_b (LMB) for unverified LASA bulletin entries. (b) NORSAR m_b (NMB) for unverified NORSAR bulletin entries.

the fact that none of the potential events from that region on Figure 6 have assigned m_b values greater than 4.2. If all the events on Figure 6 are real then these data are also not grossly inconsistent with the previously estimated worldwide 90% threshold somewhere between 4.7 and 4.9.

In general we believe that our data and methods do not justify assertions about detection thresholds which are any more precise than those we have made above.

Figure 7 is one last m_b histogram. It shows the m_b distribution of all ISM events with epicenters less than 95° and more than 30° from LASA. The shaded sections represent the counts of the events which were not reported on the LASA daily bulletin. It can be seen that LASA reported a large fraction of these events and the unreported ones, as a fraction of total events at any magnitude level, are distributed quite uniformly in magnitude. This would be the case if LASA were simply turned off for a fraction of the total ISM. In fact LASA, for various reasons, was reported not operating for a time equivalent to 8.3% of the ISM and the missing events represent 13.4% of the ISM events. An event by event check of all missing events showed that half of them were in the reported down times and the other were not. At the present time we have no satisfactory explanation for the missing events since, in our opinion, LASA should have detected most of them.

Fig. 7. Histogram of m_b (AVEMB) for ISM events located 30° - 95° from LASA. Events not on the LASA bulletin are indicated by dark shading.

Location Comparisons and Evaluation

Figure 8 is a comparison of the ISM epicenters of events with the locations given by other sources. These other sources are USGS PDE, LASA, NORSAR, and the 32-station list. Histograms of the differences in epicenters in degrees are shown. Agreement with PDE is excellent as expected. Most LASA and NORSAR epicenters are within 5° of the ISM location with nontrivial numbers of events out to 20° and occasional very large differences. The very large differences usually correspond to an incorrect phase assignment by the array in preparing the bulletin. The spread for the 32 station locations is more than for PDE but much less than for LASA or NORSAR. In fact the 32-station spread is comparable to that for the PDE when only PDE events are considered and becomes greater only when some of the more marginal events are added to the population.

A comparison of ISM depths and those of the USGS PDE, is shown as a scatter diagram in Figure 9. That Figure contains points for every PDE event which was not assigned depth 33 by PDE and which was located by us without restraining depth. It is difficult to make conclusions from these data since the relationship of neither the PDE nor ISM depth to the true one is known.

As explained elsewhere (3) our location programs find the origin time and hypocenter which minimize the goodness of fit parameter CHI2. This parameter is a weighted sum of the squares of observation residuals. The weights are obtained by inverse scaling of residuals with assigned standard deviations before squaring and summing. An error ellipsoid can be defined which corresponds to a unit increase in CHI2 from the minimum value obtained in locating an event. Our hypocenter quality variables DEPTHQ and MAXAX2 are defined in terms of this ellipsoid as indicated in

Fig. 8. Histograms of the distance (degrees) between the ISM epicenter and (a) USGS PDE epicenter, (b) LASA bulletin epicenter, (c) NORSAR bulletin epicenter, (d) 32 station ISM epicenter, for events with locations assigned by both sources involved.

Fig. 8. Continued.

Fig. 8. Continued.

Fig. 8. Continued.

Fig. 9. ISM depth (DEPTH) vs PDE depth (PDEPTH) for A, B, C, D grade ISM events with a PDE depth assigned other than 33 km. All depths in kilometers.

Figure 10. It should be noted that DEPTHQ is not just the length of the line from the center of the ellipsoid to the surface of the ellipsoid in the vertical direction. For very long narrow error ellipsoids that might be quite misleading whereas DEPTHQ would better reflect the true state of affairs. Similar comments apply to MAXAX2 and in fact to the calculation of the hypocenter ellipsoid itself from the complete four-dimensional error ellipsoid which has a time as well as three space dimensions.

Some experiments have been completed which give a more direct interpretation of the quality variables DEPTHQ and MAXAX2. One of these deals with DEPTHQ and the other with both DEPTHQ and MAXAX2. Results are described below.

For the first experiment all A grade events which included depth phases in obtaining the ISM location were selected and relocated without using the depth phases. Of these 141 converged properly without any need for restraining depth for the relocation. Since the previous locations with depth phases tended to pin the depth closely to that indicated by the depth phases we took the difference between the two depths as the actual error in depth for the relocated events. The absolute value of this error was weighted inversely by the depth quality of the relocated event and the histogram of Figure 11 generated. Accepting the assumption that the original depth was correct we see that the indicated depth of the relocated events was almost never in error by more than 2*DEPTHQ and that it was less than DEPTHQ for 75% of the relocated events.

The second experiment also started with a set of A grade ISM events. For each event the basic data used to obtain locations were split into two approximately equal disjoint sets and two new locations calculated. The absolute value of differences in the two depths were calculated and normalized by the square root of the sum of the squares of the two DEPTHQs. Similarly the length of the vector between the two epi-

Fig. 10. Cross section through hypocenter error ellipsoid showing definitions of quality parameters DEPTHQ and MAXAX2. Section is in the plane defined by the vertical and the largest principal axis of the ellipsoid.

Fig. 11. Histogram of the change in depth resulting from relocating A grade events after discarding all depth phases. Each change is normalized by the relocation depth quality parameter. Total number of events used is 141.

centers was calculated and normalized by the square root of the sum of the squares of the two MAXAX2s for each event. The particular normalizations used assume that DEPTHQ and MAXAX2 are quantities conceptually similar to standard deviations and that they will combine in the same way as standard deviations when differences of the two independent estimates are taken. Although this is not strictly correct it was felt to be a satisfactory assumption for our preliminary calibration of DEPTHQ and MAXAX2. Histograms of the normalized differences are shown on Figures 12 and 13. It can be seen that the normalized differences have about the same distribution as those of Figure 11.

We would like to be able to claim that our calibrations of DEPTHQ and MAXAX2 are absolute. Unfortunately we cannot really do this. Consider the last experiment for example and suppose an event is in an arc area with significant lateral inhomogeneities. Both of our relocations may have similar systematic errors and our calibration may thus be missleading. This question of absolute calibration is still essentially unresolved and will be the topic of future research.

One final point to be made about ISM locations is that the reliability of assigned epicenters clearly deteriorates with decreasing body wave magnitude. Figure 14 shows a plot of MAXAX2 vs AVEMB for all ISM events for which at least three stations were used in calculating AVEMB and for which MAXAX2 could be calculated. Requiring three or more stations increases the reliability of AVEMB although errors in depth or location may still introduce nontrivial errors. It can be seen that the apparent reliability indicated by MAXAX2 begins to get considerably worst for significant numbers of events when AVEMB goes below about 4.7. This is not surprising if we recall that previous discussions indicated that this probably is about the 90% worldwide incremental threshold for the ISM.

Fig. 12. Histogram of the normalized absolute value of the difference between depths obtained by locating the same event using disjoint sets of observations. Normalizing factor for each is the square root of the sum of the squares of the two DEPTHQ quality factors obtained for the event. One normalized depth error was off scale at 5.3.

Fig. 13. Histogram of the normalized difference in epicenters obtained by locating the same events with disjoint sets of observations. Normalizing factor for each is the square root of the sum of the squares of the two MAXAX2 quality variables obtained for each event.

Fig. 14. Epicenter quality parameter (MAXAX2) vs m_b (AVEMB) for all ISM events with m_b determined from an average of three or more stations.

APPENDIX I

Parameter Definitions

O. DATE:

Date (Month/Day/Year)

O.TIME:

ISM origin time (Hours:Minutes:Seconds)

LAT:

ISM Latitude (Degrees with + for North)

LONG:

ISM Longitude (Degrees with + for East)

DEPTH:

ISM Depth (Kilometers)

AVEMB:

ISM m_h (Average of single station m_h values)

NAVEMB:

Number of stations averaged to get AVEMB

MAXMB:

 $Maximum \ m_{\stackrel{}{h}} \ value \ calculated \ for \ any \ station$

MINMB:

 $Minimum \ m_h \ value \ calculated \ for \ any \ station$

NEXMB:

Number of station m_h values excluded in calculating AVEMB. Station

excluded if its m_h value is more than 0.6 units from AVEMB

DEGF:

Degrees of freedom for the ISM location and origin time estimate.

CHI2:

Sum of the square of residuals of observations from ISM origin time

and location. Residuals weighted inversely with assigned variance.

RATIO:

CHI2/DEGF

MAXAX2:

Length of the major semiaxis of the ISM epicenter error ellipse (kilo-

meters). See Figure 10

DEPTHQ:

Half length of depth error bar (kilometers). See Figure 10.

GRADE:

ISM event grade assigned as defined in Table

REGNUM:

Geographical region number of ISM event

SEISRG:

Seismic region number of ISM event

NAT:

Number of station arrival times associated with ISM event.

NV: Number of array velocity observations associated with ISM event

NATLOC: Number of station arrival times used in locating ISM event

NVLOC: Number of array velocity observations used in locating ISM events.

POTIME, PLAT, PLONG, PDEPTH, PMB: USGS PDE values corresponding to O.TIME, LAT, LONG, DEPTH, AVEMB.

PIDIST: Distance from ISM epicenter to USGS PDE epicenter (Degrees)

LOTIME, LLAT, LONG, LDEPTH, LMB: LASA bulletin values corresponding to O.TIME, LAT, LONG, DEPTH, AVEMB.

LIDIST: Distance from ISM epicenter to LASA bulletin epicenter (Degrees)

NOTIME, NLAT, NLONG, NDEPTH, NMB: NORSAR bulletin values corresponding to O.TIME, LAT, LONG, DEPTH, AVEMB

NIDIST: Distance from ISM epicenter to NORSAR bulletin epicenter (Degrees)

XOTIME. . . XNVLOC: 32-station values for similarly named ISM variables without the leading "X".

A list of seismic events for the period 20 February to 19 March 1972 (The International Seismic Month — ISM) has been compiled using short-period data from a large number of seismic stations and arrays. Hypocenters and other parameters have been obtained for every event and are presented along with comparisons with other event lists for the same time period. Also included are the results of experiments designed to calibrate certain parameters which have been selected to indicate the accuracy of estimated depths and epicenters. The ISM list contains 996 verified events.
